During normal morphogenesis, epithelial cells secrete components of the basement membrane, as well as contractile proteins, which attach the epithelium to underlying extracellular matrix. Intracellular assembly of basement membrane is achieved by localized adhesion and elongation of the membrane. Although epithelial morphogenesis is commonly associated with cell movement, such as epithelial cell sheeting, relatively little is known about the molecular control of adhesive forces during embryonic morphogenesis. In this study, computer-based three-dimensional analysis of epithelial cell-matrix adhesion was performed and a model of basement membrane assembly was constructed in two dimensions. The first mathematical model illustrates the change in cell shape, and the second
